

Patent claims

1. An installation for processing continuous materials, comprising a roll arrangement for guiding the continuous material, having a deflection and/or pressure roll and an application device interacting with said deflection and/or pressure roll, for applying a fluid to the continuous material, characterized in that the application device is constructed as a structural unit and is separably connected to the processing installation, the deflection and/or pressure roll being arranged on the processing installation in such a way that, when the application device is separated, the deflection and/or pressure roll remains on the processing installation.
2. The apparatus as claimed in claim 1, characterized in that the application device is a structural unit which is provided with a slot-like application region, which is arranged in the wrap region of the continuous material on the deflection and/or pressure roll for applying the fluid.
3. The apparatus as claimed in claim 2, wherein the slot-like application region comprises a fishtail die.
4. The apparatus as claimed in claim 1, characterized in that the application device is a structural unit which has at least one application roll for conveying the fluid, which roll is arranged in the wrap region of the continuous material on the deflection and/or pressure roll.
5. The apparatus as claimed in claim 4, characterized in that the application roll is a roll with a profiled surface,

which in particular has depressions for conveying the fluid.

6. The apparatus as claimed in claim 1, characterized in that the application device is a structural unit having a spraying apparatus which applies the fluid and is arranged in the wrap region of the continuous material on the deflection and/or pressure roll.
7. The apparatus as claimed in claim 1, characterized in that the application device is a structural unit having a casting apparatus which applies the fluid and is arranged in the wrap region of the continuous material on the deflection and/or pressure roll.
8. The apparatus as claimed in claim 1, characterized in that an arrangement for supplying a substrate is provided downstream of the application device is, by means of which arrangement the substrate can be laminated with the continuous material by means of the fluid applied.
9. The apparatus as claimed in claim 1, characterized in that a second application device for a fluid is provided, which is connected downstream of the first application device, is constructed as a structural unit and is separably connected to the processing installation, a second deflection and/or pressure roll being arranged on the installation in such a way that, when the second application device is separated, the second deflection and/or pressure roll remains on the processing installation.
10. The apparatus as claimed in claim 9, characterized in that provided downstream of the second modular application de-

vice is an arrangement for supplying a second substrate, by means of which arrangement the second substrate can be laminated with the continuous material or the first substrate by means of the fluid applied.

11. An installation for processing continuous materials, comprising a roll arrangement for guiding a continuous material and a first application device, arranged in the wrap region of the continuous material on a deflection and/or pressure roll, for a fluid, characterized in that a second application device for fluids is provided, which device is arranged in the wrap region of the continuous material on a deflection and/or pressure roll, and in that an arrangement for supplying a second substrate is provided, comprising a deflection and/or pressure roll.
